(57) **ABSTRACT**

The present invention aims at providing an antistatic pressure-sensitive adhesive optical film exhibiting excellent antistatic effect, optical properties, and water resistance and having excellent adhesion between the antistatic layer and the pressure-sensitive adhesive layer. An antistatic pressure-sensitive adhesive optical film, the optical film having an antistatic layer laminated on at least one side of the optical film, and a pressure-sensitive adhesive layer further laminated on the antistatic layer, wherein the antistatic layer comprises a conductive polymer and a sulfonic acid compound as raw material components, and the pressure-sensitive adhesive layer is formed of an acryl-based pressure-sensitive adhesive containing nitrogen.

ANTISTATIC ADHESIVE OPTICAL FILM AND IMAGE DISPLAY

This application is the U.S. National Phase under 35 U.S.C. §371 of International Application No. PCT/JP2005/018762, filed Oct. 12, 2005, which claims priority to Japanese Patent Application No. 2004-306946, filed Oct. 21, 2004. The International Application was not published in English under PCT Article 21(2).

TECHNICAL FIELD

The present invention relates to an antistatic pressure-sensitive adhesive optical film having an antistatic layer laminated on at least one side of an optical film, and having a pressure-sensitive adhesive layer further laminated on the antistatic layer. Furthermore, it relates to an image viewing display using the above-mentioned antistatic pressure-sensitive adhesive optical film, such as liquid crystal displays (LCDs), organic electroluminescence viewing displays, and PDPs. As the optical films, a polarizing plate, a retardation plate, an optical compensation film, a brightness enhancement film, etc., and furthermore optical films with the films laminated to each other may be mentioned.

BACKGROUND ART

In liquid crystal displays etc., an image forming system necessarily requires polarizing elements disposed on both sides of a liquid crystal cell, and in general, polarizing plates are adhered thereto. Moreover, in liquid crystal panels, in order to improve display quality of displays, various optical elements in addition to the polarizing plates are increasingly used. For example, retardation plates for prevention of coloring, viewing-angle expansion films for improving viewing angle of liquid crystal displays, and furthermore, brightness enhancement films for increasing contrast of displays etc. are used. These films are generically named and called optical films.

In these optical films, in order to prevent occurrence of damage and contamination to a surface of the optical film in transportation or manufacturing process until it is sent to consumers, surface protective films are usually attached on a surface thereof. The surface protective film is attached from a stage in which the optical film is in a state of single substance, and in some case it is peeled after being attached onto an LCD etc., and furthermore in other cases it is attached again after peeled to a same or another surface protective film. And there have been problems that static electricity generated in case of peeling of the surface protective film may destroy circuits, such as in LCD panels. This static electricity affects array elements in the LCD panel and further affects alignment of the liquid crystal and induces problems of defects. The surface protective film will give the same problems due to friction of the optical films not only in peeling, but in the manufacturing process, or in the use by consumers. In order to solve the problems, there has been proposed application of antistatic property to optical films, such as polarizing plate. For example, disclosed are optical films with an antistatic layer having a layer provided on the surface of the optical film, and optical films having a transparent conductive layer provided on one side or both sides of the optical films.

When attaching an optical film on a liquid crystal cell, pressure-sensitive adhesives are usually used. Furthermore, in adhesion between optical films and liquid crystal cells or between optical films, each material are usually attached together using pressure-sensitive adhesives in order to reduce

loss of light. In such a case, since advantages such as omission of drying step for fixing optical films may be given, generally used is a pressure-sensitive adhesive optical film having a pressure-sensitive adhesive layer beforehand provided on one side of the optical film.

The pressure-sensitive adhesive optical films are cut into a size of a display in use. In the case of handling in use, touch of an edge (cut section) of the pressure-sensitive adhesive optical film by operators and by apparatuses may cause possible lack of the pressure-sensitive adhesive in the touched portion. Attachment of the pressure-sensitive adhesive optical film having such lack of the pressure-sensitive adhesive to the liquid crystal cells fails to provide proper adhesion in the lack portion, and therefore, the portion gives reflection of light, causing possible problems of display defects. In particular, in these days, since narrower edges of displays are needed, even defects created at the edges significantly reduce display quality. Furthermore, when peeling of the film from the panel is necessary due to inclusion of foreign matters, etc., after attachment of the pressure-sensitive adhesive optical film to the liquid crystal panel, avoidance of trouble of residue of the pressure-sensitive adhesive (what is called adhesive residue phenomenon) around the side of the panel, that is, excellent reworkability will be needed.

And it is also proposed to provide antistatic property to the above-described pressure-sensitive adhesive optical films. For example, it is proposed that antistatic property is provided to an antiglare layer by inclusion of electric conductive particles in the antiglare layer on the surface of a polarizing plate simultaneously having a pressure-sensitive adhesive layer on an opposite side (Japanese Patent Application Laid-Open No. 10-239521). However, the method in Japanese Patent Application Laid-Open No. 10-239521 has difficulty in maintenance of physical property as an antiglare layer, and therefore shows limited stability. In providing an antistatic layer to a pressure-sensitive adhesive optical film, in order to cancel poor alignment of the liquid crystal cell caused by application of a voltage that happens within the panel, it is preferred to provide the antistatic layer between the optical film and the pressure-sensitive adhesive layer. Antistatic pressure-sensitive adhesive optical films having an antistatic layer provided between an optical film and a pressure-sensitive adhesive layer has a problem of omission of a pressure-sensitive adhesive and adhesive residue, and a problem of reworkability. A method of inclusion of conductive substances in a pressure-sensitive adhesive layer is proposed as a method of giving antistatic function to an optical film (Japanese Patent Application Laid-Open No. 2003-294951). However, the method in Japanese Patent Application Laid-Open No. 2003-294951 has difficulty in maintenance of physical property as a pressure-sensitive adhesive layer, therefore shows limited stability.

SUMMARY OF THE INVENTION

The present invention aims at providing an antistatic pressure-sensitive adhesive optical film exhibiting excellent antistatic effect, optical properties, and water resistance and having excellent adhesion between the antistatic layer and the pressure-sensitive adhesive layer, wherein an antistatic layer is laminated on at least one side of a optical film and a pressure-sensitive adhesive layer is further laminated on the antistatic layer. Furthermore, the present invention aims at providing an image viewing display using the antistatic pressure-sensitive adhesive optical film.

As a result of repeated wholehearted investigation performed by the present inventors for solving the problem, it has

been found out that the problem may be solved by the following antistatic pressure-sensitive adhesive optical film, leading to completion of the present invention.

That is, the present invention relates to an antistatic pressure-sensitive adhesive optical film, the optical film having an antistatic layer laminated on at least one side of an optical film, and a pressure-sensitive adhesive layer further laminated on the antistatic layer, wherein the antistatic layer includes a conductive polymer and a sulfonic acid compound as raw material components, and the pressure-sensitive adhesive layer is formed of an acryl-based pressure-sensitive adhesive including nitrogen.

An antistatic pressure-sensitive adhesive optical film exhibiting excellent antistatic effect, optical properties, and water resistance, and having excellent adhesive property between the antistatic layer and the pressure-sensitive adhesive layer may be provided by disposing an antistatic layer including a conductive polymer and a sulfonic acid compound as raw material components between the optical film and the pressure-sensitive adhesive layer, and by forming the pressure-sensitive adhesive layer with an acryl-based pressure-sensitive adhesive containing nitrogen.

Specifically, an antistatic layer formed between the optical film and the pressure-sensitive adhesive layer exhibits excellent antistatic effect, and can suppress generation of static electricity by peeling of a surface protective film or by friction of optical films, leading to prevention of breakage of circuits, or of alignment defects of liquid crystals. Furthermore, since a sulfonic acid compound (dopant) is used with the conductive polymer as a raw material component of the antistatic layer, reaction of apart of the conductive polymer and the sulfonic acid compound forms a sulfonate. It is probable that this sulfonate works to improve the conductivity of the antistatic layer. Although, in case of addition of sulfonic acid compound as a dopant, conventional pressure-sensitive adhesive layers consisting of acryl-based pressure-sensitive adhesives induced problems in adhesive properties of the antistatic layer and the pressure-sensitive adhesive layer, it was found out that use of acryl-based pressure-sensitive adhesives containing nitrogen can improve the adhesive properties between the both layers. Thereby, missing of some of the pressure-sensitive adhesive caused by contact between film ends during handling of the antistatic pressure-sensitive adhesive optical film, and adhesive residue at the time of reworking of the liquid crystal panels can be greatly reduced, resulting in improvement in the handling property of the antistatic pressure-sensitive adhesive optical film or in the optical property of the optical film.

The conductive polymer is preferably water soluble or water dispersible. This water soluble or water dispersible conductive polymer is preferably of polythiophene-based conductive polymer.

In addition, the base polymer of the acryl-based pressure-sensitive adhesives containing nitrogen is preferably a copolymer of a monomer containing nitrogen and an acryl-based monomer, or a mixture of a polymer containing nitrogen and an acryl-based polymer.

The present invention relates to an image viewing display that uses at least one sheet of the antistatic pressure-sensitive adhesive optical film. In use of the antistatic pressure-sensitive adhesive optical film of the present invention, one of the film may be used independently or two or more of the films may be used in combination according to various kinds of use of the image viewing displays, such as liquid crystal viewing displays.

BRIEF DESCRIPTION OF THE DRAWING

FIG. 1 illustrates an example of a cross section of an antistatic pressure-sensitive adhesive optical film of the present invention.

DESCRIPTION OF THE PREFERRED EMBODIMENT

As illustrated in FIG. 1, in an antistatic pressure-sensitive adhesive optical film of the present invention, an antistatic layer 2 and a pressure-sensitive adhesive layer 3 are laminated on one side of an optical film 1 in this order. In FIG. 1, the pressure-sensitive adhesive layer 3 is formed on one side of the optical film 1, however, the pressure-sensitive adhesive layer 3 may be formed on both sides of the optical film. In addition, the pressure-sensitive adhesive layer 3 on another side may have an antistatic layer 2.

The antistatic layer 2 of the antistatic pressure-sensitive adhesive optical film according to the present invention includes a conductive polymer that is an antistatic agent, and a sulfonic acid compound that is a dopant, as a raw material component.

Conductive polymers having excellent optical properties, external appearance and antistatic effect, and having excellent stability of the antistatic effect in a heated condition and in a humidified condition are used as conductive polymers. Such conductive polymers include polymers, such as polyaniline, polythiophene, polypyrrole, and polyquinoxaline. Of these polymers, polyaniline, polythiophene, etc. that easily become water-soluble conductive polymers or water dispersible conductive polymers are preferably used. In particular, polythiophene is preferred.

Use of the water soluble conductive polymer or water dispersible conductive polymer allows preparation of an application liquid in forming an antistatic layer as an aqueous solution or a water dispersion, and can not require use of organic solvents in the application liquid, and thereby can suppress deterioration and degradation of base materials of the optical film caused by the organic solvents. It is preferred, from the point of adhesion, to use only water as solvents for the aqueous solution or water dispersion, but hydrophilic solvents may also be included. The hydrophilic solvents include, for example, alcohols, such as methanol, ethanol, n-propanol, isopropanol, n-butanol, isobutanol, sec-butanol, tert-butanol, n-amyl alcohol, isoamyl alcohol, sec-amyl alcohol, tert-amyl alcohol, 1-ethyl-1-propanol, 2-methyl-1-butanol, n-hexanol, cyclohexanol, etc.

The weight average molecular weight expressed in terms of polystyrene of the water soluble or water dispersible polyaniline is preferably 500000 or less, and more preferably 300000 or less. The weight average molecular weight expressed in terms of polystyrene of the water soluble or water dispersible polythiophene is preferably 400000 or less, and more preferably 300000 or less. The weight average molecular weight exceeding the value cannot likely satisfy the water solubility or water dispersibility. Preparation of the application liquid (aqueous solution or water dispersion) by use of such polymer tends to make solid content of polymer remain in the application liquid, or to give the application liquid having a higher viscosity, leading to difficulty of formation of an antistatic layer with a uniform thickness.

The water solubility of the water soluble electric conductive polymer represents a water solubility having 5 g or more of solubility to 100 g of water. The solubility of the electric conductive polymer to 100 g of water is preferably 20 to 30 g. The water dispersible conductive polymer is a polymer that

allows dispersion of conductive polymers, such as polyaniline and polythiophene in a particle-shaped state in water, and the water dispersion has a lower viscosity of liquid, can provide easy formation of a thinner film, and further enables a uniform applied layer. Here, from the view point of the uniformity of the antistatic layer, the size of 1 μm or less of the particles is preferred.

Furthermore, it is preferred that the water soluble conductive polymer or water dispersible conductive polymer, such as polyaniline and polythiophene as described above, have hydrophilic functional group in the molecule thereof. The hydrophilic functional groups include, for example, a sulfone group, amino group, amido group, imino group, quaternary-ammonium-salt group, hydroxyl group, mercapto group, hydrazino group, carboxyl group, sulfate group, phosphoric ester group, or salts of the above-mentioned groups, etc. Inclusion of the hydrophilic functional group in the molecule improves solubility to water, or allows easy dispersion in a particle shape in water, leading to easier preparation of the water soluble conductive polymer or water dispersible conductive polymer.

As examples of commercially available water soluble conductive polymers, a polyaniline sulfonic acid (manufactured by Mitsubishi Rayon Co., Ltd., weight average molecular weight expressed in terms of polystyrene 150000) etc. may be mentioned. As examples of commercially available water dispersible conductive polymers, a polythiophene based conductive polymer (manufactured by Nagase Chemtech Co., Ltd., trade name, Denatron series) etc. may be mentioned.

The sulfonic acid compounds include, for example, p-toluenesulfonic acid, benzenesulfonic acid, ethylbenzene sulfonic acid, octylbenzenesulfonic acid, dodecylbenzenesulfonic acid, mesitylene sulfonic acid, m-xylene sulfonic acid, polystyrene sulfonic acid, polyvinyl sulfonic acid, etc. These may be used independently and two or more kinds may be used in combination. In preparation of the aqueous application liquid using the water soluble conductive polymer or the water dispersible conductive polymer described above, it is preferred to use water soluble sulfonic acid compounds, such as polystyrene sulfonic acid and polyvinyl sulfonic acid, for improvement in solubility or dispersibility of the conductive polymer.

An amount of 100 to 300 parts by weight of the sulfonic acid compound with respect to 100 parts by weight of the conductive polymer is preferably used, and more preferably 150 to 250 parts by weight. The amount of addition of the sulfonic acid compound less than 100 parts by weight gives less amount of the sulfonate formed by reaction of the conductive polymer and the sulfonic acid compound, and tends to provide insufficient antistatic function, or insufficient improvement effect of the adhesion between the antistatic layer and the pressure-sensitive adhesive layer. On the other hand, the amount of addition exceeding 300 parts by weight substantially tends not to provide effects on the antistatic function, and on the adhesion between the antistatic layer and the pressure-sensitive adhesive layer.

Binder components may be used, in combination, in formation materials of the antistatic layer for the purpose of improvement of film-forming property of the antistatic agent, and adhesion with respect to the optical film, etc. In use of the water soluble conductive polymer or the water dispersible conductive polymer as an antistatic agent, it is preferred to use water soluble or water dispersible binder components. The binder components include, for example, polyurethane-based resins, polyester-based resins, acryl-based resins, polyether-based resins, cellulose-based resins, polyvinyl alcohol-based resins, epoxy resins, polyvinyl pyrrolidones, polystyrene-

based resins, polyethylene glycol, pentaerythritol, etc. Polyurethane-based resins, polyester-based resins, and acryl-based resins are especially preferred. These binder components may be suitably used independently, and two or more kinds may be used in combination according to usages. Although dependent on kinds of conductive polymers, the amount of the binder component used is usually 20 to 5000 parts by weight with respect to 100 parts by weight of the conductive polymer, and preferably 50 to 1500 parts by weight.

The surface electric resistance value of the antistatic layer is preferably $1 \times 10^{12} \Omega/\text{square}$ or less, and more preferably $1 \times 10^{11} \Omega/\text{square}$ or less. The surface electric resistance value exceeding $1 \times 10^{12} \Omega/\text{square}$ cannot exhibit sufficient antistatic function. Therefore, it causes peeling of the surface protective film, generates static electricity by friction of the optical film, and possibly causes electrification to induce breakage of circuits of the liquid crystal cell and alignment defect of the liquid crystal.

As a pressure-sensitive adhesive for forming a pressure-sensitive adhesive layer 3 of an antistatic pressure-sensitive adhesive optical film according to the present invention, an acryl-based pressure-sensitive adhesives containing nitrogen is used. The acryl-based pressure-sensitive adhesive has excellent optical transparency, exhibits suitable pressure-sensitive adhesive properties such as wettability, cohesiveness, and adhesion, and has excellent weather resistance, heat-resisting property, etc.

The base polymer of the acryl-based pressure-sensitive adhesives containing nitrogen is preferably made of copolymers (acrylic polymer containing nitrogen) of monomers containing nitrogen and acryl-based monomer or of a mixture of polymer containing nitrogen and acryl-based polymer.

The monomer containing nitrogen in particular will not be limited as long as they are vinyl monomers containing a nitrogen atom, and examples thereof include, for example, maleimide, N-vinyl pyrrolidone, primary amines, secondary amines, tertiary amines, and quaternary ammonium salts of (meth)acryl-based monomer, and (meth)acrylamide, etc. Specifically, examples thereof include N-cyclohexylmaleimide, N-phenylmaleimide, N-acryloyl morpholine, N,N-(dimethylamino)ethyl(meth)acrylate, N,N-(dimethylamino)propyl(meth)acrylate, 3-(3-pyridinyl)propyl (meth)acrylate, N,N-dimethyl(meth)acrylamide, N,N-diethyl(meth)acrylamide, N-methyl(meth)acrylamide, N-ethyl(meth)acrylamide, and N-hexyl(meth)acrylamide, etc. These may be independently used and two or more kinds may be used in combination.

Alkyl (meth)acrylates having alkyl groups with 4 to 12 carbon atoms are suitably used as an acryl-based monomer. Specifically, the acryl-based monomer includes butyl (meth)acrylate, 2-ethylhexyl (meth)acrylate, isooctyl methacrylate, n-octyl (meth)acrylate, isononyl (meth)acrylate, lauryl (meth)acrylate, etc. These may be independently used and two or more kinds may be used in combination.

In the case of acryl-based polymer containing nitrogen, copolymerization of 0.5 to 50 parts by weight of a monomer containing nitrogen with respect to 100 parts by weight of the alkyl (meth)acrylate is preferred, and more preferably 1 to 30 parts by weight. The copolymerization of the monomer containing nitrogen less than 0.5 parts by weight tends not to sufficiently improve the adhesion between the antistatic layer and the pressure-sensitive adhesive layer, and on the other hand, the copolymerization of the monomer exceeding 50 parts by weight tends to make initial adhesion poorer.

For the purpose of improvement of adherability and heat-resistance, one or more kinds of various monomers may be

introduced into the acryl-based polymer containing nitrogen by copolymerization. Examples of such monomers for copolymerization include, for example, monomers containing a hydroxyl group, such as 2-hydroxyethyl(meth)acrylate, 2-hydroxypropyl(meth)acrylate, 4-hydroxybutyl(meth)acrylate, 6-hydroxyhexyl(meth)acrylate, 8-hydroxyoctyl(meth)acrylate, 10-hydroxydecyl(meth)acrylate, 12-hydroxylauryl(meth)acrylate, (4-hydroxymethylcyclohexyl)-methyl acrylate, etc.; monomers containing a carboxyl group such as (meth)acryl-based acid, carboxyethyl(meth)acrylate, carboxypentyl(meth)acrylate, itaconic acid, maleic acid, fumaric acid, crotonic acid, etc.; monomers containing an acid anhydride group, such as maleic anhydride and itaconic acid anhydride; caprolactone additive of acrylic acid; monomers containing a sulfonic acid group, such as styrene sulfonic acid, allylsulfonic acid, sulfopropyl(meth)acrylate, (meth)acryloyloxy naphthalenesulfonic acid, etc.; monomers containing a phosphoric acid group, such as 2-hydroxyethyl acryloyl phosphate, etc.

Furthermore, examples of such monomers for copolymerization also include, vinyl-based monomers such as vinyl acetate, vinyl propionate, styrene, and α -methyl styrene; acryl-based monomers containing an epoxy group such as glycidyl(meth)acrylate; glycol-based acrylate monomers such as polyethylene glycol(meth)acrylate, polypropylene glycol(meth)acrylate, methoxyethylene glycol(meth)acrylate, methoxypolypropylene glycol(meth)acrylate etc.; acrylate-based monomers such as tetrahydrofurfuryl(meth)acrylate, fluorinated(meth)acrylate, silicone(meth)acrylate, 2-methoxy ethyl acrylate, etc.

Of these polymers, in view of adherability to liquid crystal cells and adhesive durability as optical film usages, monomers containing a carboxyl group, such as acrylic acid, are preferably used.

The proportion of the copolymerization monomer in the acryl-based polymer containing nitrogen is not in particular limited, and it is preferably approximately 0.1 to 10% in weight ratio.

An average molecular weight of the acryl-based polymer containing nitrogen is not especially limited, and the weight average molecular weight is preferably approximately 300000 to 2500000. The acryl-based polymer containing nitrogen may be produced by various publicly known methods, and for example radical-polymerization methods, such as bulk polymerization method, solution-polymerization method, and suspension-polymerization method, may be suitably selected. As radical polymerization initiators, various kinds of publicly known initiators, such as an azo-based and peroxide-based initiator, may be used. Reaction temperature is usually approximately 50 to 80° C., and reaction period is 1 to 8 hours. Furthermore, of the manufacturing methods, the solution-polymerization method is preferred and, generally ethyl acetate, toluene, etc. are used as a solvent. The solution concentration is usually approximately 20 to 80% by weight.

The base polymer of the acryl-based pressure-sensitive adhesives containing nitrogen may be a mixture of a polymer containing nitrogen obtained by polymerization of the monomer containing nitrogen (and a monomer for copolymerization), and an acryl-based polymer obtained by polymerization of the acryl-based monomer (and a monomer for copolymerization).

The polymer containing nitrogen is preferably 0.5 to 50 parts by weight with respect to 100 parts by weight of the acryl-based polymer, and more preferably 1 to 30 parts by weight. The polymer containing nitrogen less than 0.5 parts by weight tends not sufficiently to improve adhesion between

the antistatic layer and the pressure-sensitive adhesive layer, and on the other hand, the polymer containing nitrogen exceeding 50 parts by weight tends to give poor initial adhesion.

The pressure-sensitive adhesive is preferably a pressure-sensitive adhesive composition including cross linking agents. Multifunctional compounds that can be blended with the pressure-sensitive adhesive include organic cross linking agents and polyfunctional metal chelates. The organic cross linking agents include epoxy-based cross linking agents, isocyanate-based cross linking agents, imine-based cross linking agents, etc. As organic cross linking agents, isocyanate-based cross linking agents are preferred. Polyfunctional metal chelates are obtained by covalent bonding or coordinate bonding polyvalent metals with organic compounds. The polyvalent metal atoms include Al, Cr, Zr, Co, Cu, Fe, Ni, V, Zn, In, Ca, Mg, Mn, Y, Ce, Sr, Ba, Mo, La, Sn, Ti, etc. Atoms in the organic compounds capable of covalent bonding or coordinate bonding include an oxygen atom, etc., and the organic compounds include alkyl esters, alcohol compounds, carboxylic acid compounds, ether compounds, ketone compounds, etc.

The proportion of blending of the base polymer and the cross linking agent is not in particular limited, and the cross linking agent (solid content) is preferably approximately 0.01 to 10 parts by weight with respect to 100 parts by weight of the base polymer (solid content), and more preferably approximately 0.1 to 5 parts by weight.

Furthermore, various kinds of additives such as tackifiers, plasticizers, fillers including glass fibers, glass beads, metal powders, other inorganic powders, pigments, colorants, fillers, antioxidants, ultraviolet absorbers, silane coupling agents, etc. may also be suitably used as the pressure-sensitive adhesive, if needed, in the range that does not depart from objects of the present invention. The pressure-sensitive adhesive may also be used as a pressure-sensitive adhesive layer exhibiting light diffusibility by inclusion of particles.

As optical film 1 used for the antistatic pressure-sensitive adhesive optical film of the present invention, optical films used for formation of image viewing displays, such as liquid crystal viewing displays, may be used, and the kind is not limited in particular. For example, polarizing plates may be illustrated as the optical films. Polarizing plates having a transparent protective film one side or both sides of a polarizer is generally used.

A polarizer is not limited especially but various kinds of polarizer may be used. As a polarizer, for example, a film that is uniaxially stretched after having dichromatic substances, such as iodine and dichromatic dye, absorbed to hydrophilic high molecular weight polymer films, such as polyvinyl alcohol type film, partially formalized polyvinyl alcohol type film, and ethylene-vinyl acetate copolymer type partially saponified film; poly-ene type orientation films, such as dehydrated polyvinyl alcohol and dehydrochlorinated polyvinyl chloride, etc. may be mentioned. In these, a polyvinyl alcohol type film on which dichromatic materials (iodine, dyes) is absorbed and oriented after stretched is suitably used. Although thickness of polarizer is not especially limited, the thickness of about 5 to 80 μ m is commonly adopted.

A polarizer that is uniaxially stretched after a polyvinyl alcohol type film dyed with iodine is obtained by stretching a polyvinyl alcohol film by 3 to 7 times the original length, after dipped and dyed in aqueous solution of iodine. If needed the film may also be dipped in aqueous solutions, such as boric acid and potassium iodide, which may include zinc sulfate, zinc chloride. Furthermore, before dyeing, the polyvinyl alcohol type film may be dipped in water and rinsed if needed.

By rinsing polyvinyl alcohol type film with water, effect of preventing un-uniformity, such as unevenness of dyeing, is expected by making polyvinyl alcohol type film swelled in addition that also soils and blocking inhibitors on the polyvinyl alcohol type film surface may be washed off. Stretching may be applied after dyed with iodine or may be applied concurrently, or conversely dyeing with iodine may be applied after stretching. Stretching is applicable in aqueous solutions, such as boric acid and potassium iodide, and in water bath.

As the protective film prepared on one side or both sides of the polarizer, materials is excellent in transparency, mechanical strength, heat stability, water shielding property, isotropy, etc. may be preferably used. As materials of the above-mentioned protective layer, for example, polyester type polymers, such as polyethylene terephthalate and polyethyleneterephthalate; cellulose type polymers, such as diacetyl cellulose and triacetyl cellulose; acrylics type polymer, such as polymethylmethacrylate; styrene type polymers, such as polystyrene and acrylonitrile-styrene copolymer (AS resin); polycarbonate type polymer may be mentioned. Besides, as examples of the polymer forming a protective film, polyolefin type polymers, such as polyethylene, polypropylene, polyolefin that has cyclo-type or norbornene structure, ethylene-propylene copolymer; vinyl chloride type polymer; amide type polymers, such as nylon and aromatic polyamide; imide type polymers; sulfone type polymers; polyether sulfone type polymers; polyether-ether ketone type polymers; polyphenylene sulfide type polymers; vinyl alcohol type polymer; vinylidene chloride type polymers; vinyl butyral type polymers; allylate type polymers; polyoxymethylene type polymers; epoxy type polymers; or blend polymers of the above-mentioned polymers may be mentioned. Films made of heat curing type or ultraviolet ray curing type resins, such as acryl based, urethane based, acryl urethane based, epoxy based, and silicone based, etc. may be mentioned.

Moreover, as is described in Japanese Patent Laid-Open Publication No. 2001-343529 (WO01/37007), polymer films, for example, resin compositions including (A) thermoplastic resins having substituted and/or non-substituted imido group is in side chain, and (B) thermoplastic resins having substituted and/or non-substituted phenyl and nitrile group in side chain may be mentioned. As an illustrative example, a film may be mentioned that is made of a resin composition including alternating copolymer comprising iso-butylene and N-methyl maleimide, and acrylonitrile-styrene copolymer. A film comprising mixture extruded article of resin compositions etc. may be used.

In general, a thickness of the protection film, which can be determined arbitrarily, is 1 through 500 μm , preferably 5 through 200 μm in viewpoint of strength, work handling and thin layer.

Moreover, it is preferable that the protective film may have as little coloring as possible. Accordingly, a protective film having a phase difference value in a film thickness direction represented by $R_{th} = [(n_x + n_y)/2 - n_z] \times d$ of -90 nm through $+75$ nm (where, n_x and n_y represent principal indices of refraction in a film plane, n_z represents refractive index in a film thickness direction, and d represents a film thickness) may be preferably used. Thus, coloring (optical coloring) of polarizing plate resulting from a protective film may mostly be cancelled using a protective film having a phase difference value (R_{th}) of -90 nm through $+75$ nm in a thickness direction. The phase difference value (R_{th}) in a thickness direction is preferably -80 nm through $+60$ nm, and especially preferably -70 nm through $+45$ nm.

As a protective film, if polarization property and durability are taken into consideration, cellulose based polymer, such as triacetyl cellulose, is preferable, and especially triacetyl cellulose film is suitable. In addition, when the protective films are provided on both sides of the polarizer, the protective films comprising same polymer material may be used on both of a front side and a back side, and the protective films comprising different polymer materials etc. may be used. Adhesives are used for adhesion processing of the above described polarizer and the protective film. As adhesives, isocyanate derived adhesives, polyvinyl alcohol derived adhesives, gelatin derived adhesives, vinyl polymers derived latex type, aqueous polyurethane based adhesives, aqueous polyesters derived adhesives, etc. may be mentioned.

A hard coat layer may be prepared, or antireflection processing, processing aiming at sticking prevention, diffusion or anti glare may be performed onto the face on which the polarizing film of the above described protective film has not been adhered.

A hard coat processing is applied for the purpose of protecting the surface of the polarizing plate from damage, and this hard coat film may be formed by a method in which, for example, a curable coated film with excellent hardness, slide property etc. is added on the surface of the protective film using suitable ultraviolet curable type resins, such as acrylic type and silicone type resins. Antireflection processing is applied for the purpose of antireflection of outdoor daylight on the surface of a polarizing plate and it may be prepared by forming an antireflection film according to the conventional method etc. Besides, a sticking prevention processing is applied for the purpose of adherence prevention with adjoining layer.

In addition, an anti glare processing is applied in order to prevent a disadvantage that outdoor daylight reflects on the surface of a polarizing plate to disturb visual recognition of transmitting light through the polarizing plate, and the processing may be applied, for example, by giving a fine concavo-convex structure to a surface of the protective film using, for example, a suitable method, such as rough surfacing treatment method by sandblasting or embossing and a method of combining transparent fine particle. As a fine particle combined in order to form a fine concavo-convex structure on the above-mentioned surface, transparent fine particles whose average particle size is 0.5 to 50 μm , for example, such as inorganic type fine particles that may have conductivity comprising silica, alumina, titania, zirconia, tin oxides, indium oxides, cadmium oxides, antimony oxides, etc., and organic type fine particles comprising cross-linked of non-cross-linked polymers may be used. When forming fine concavo-convex structure on the surface, the amount of fine particle used is usually about 2 to 50 weight part to the transparent resin 100 weight part that forms the fine concavo-convex structure on the surface, and preferably 5 to 25 weight part. An anti glare layer may serve as a diffusion layer (viewing angle expanding function etc.) for diffusing transmitting light through the polarizing plate and expanding a viewing angle etc.

In addition, the above-mentioned antireflection layer, sticking prevention layer, diffusion layer, anti glare layer, etc. may be built in the protective film itself, and also they may be prepared as an optical layer different from the protective layer.

An optical film of the present invention is especially no limitation about the optical layers, which may be used for formation of a liquid crystal display etc., such as a reflector, a transfective plate, a retardation plate (a half wavelength plate and a quarter wavelength plate included), and a viewing angle compensation film, may be used.

Especially preferable polarizing plates are; a reflection type polarizing plate or a transfective type polarizing plate in which a reflector or a transfective reflector is further laminated onto a polarizing plate of the present invention; an elliptically polarizing plate or a circular polarizing plate in which a retardation plate is further laminated onto the polarizing plate; a wide viewing angle polarizing plate in which a viewing angle compensation film is further laminated onto the polarizing plate; or a polarizing plate in which a brightness enhancement film is further laminated onto the polarizing plate.

A reflective layer is prepared on a polarizing plate to give a reflection type polarizing plate, and this type of plate is used for a liquid crystal display in which an incident light from a view side (display side) is reflected to give a display. This type of plate does not require built-in light sources, such as a backlight, but has an advantage that a liquid crystal display may easily be made thinner. A reflection type polarizing plate may be formed using suitable methods, such as a method in which a reflective layer of metal etc. is, if required, attached to one side of a polarizing plate through a transparent protective layer etc.

As an example of a reflection type polarizing plate, a plate may be mentioned on which, if required, a reflective layer is formed using a method of attaching a foil and vapor deposition film of reflective metals, such as aluminum, to one side of a matte treated protective film. Moreover, a different type of plate with a fine concavo-convex structure on the surface obtained by mixing fine particle into the above-mentioned protective film, on which a reflective layer of concavo-convex structure is prepared, may be mentioned. The reflective layer that has the above-mentioned fine concavo-convex structure diffuses incident light by random reflection to prevent directivity and glaring appearance, and has an advantage of controlling unevenness of light and darkness etc. Moreover, the protective film containing the fine particle has an advantage that unevenness of light and darkness may be controlled more effectively, as a result that an incident light and its reflected light that is transmitted through the film are diffused. A reflective layer with fine concavo-convex structure on the surface effected by a surface fine concavo-convex structure of a protective film may be formed by a method of attaching a metal to the surface of a transparent protective layer directly using, for example, suitable methods of a vacuum evaporation method, such as a vacuum deposition method, an ion plating method, and a sputtering method, and a plating method etc.

Instead of a method in which a reflection plate is directly given to the protective film of the above-mentioned polarizing plate, a reflection plate may also be used as a reflective sheet constituted by preparing a reflective layer on the suitable film for the transparent film. In addition, since a reflective layer is usually made of metal, it is desirable that the reflective side is covered with a protective film or a polarizing plate etc. when used, from a view point of preventing deterioration in reflectance by oxidation, of maintaining an initial reflectance for a long period of time and of avoiding preparation of a protective layer separately etc.

In addition, a transfective type polarizing plate may be obtained by preparing the above-mentioned reflective layer as a transfective type reflective layer, such as a half-mirror etc. that reflects and transmits light. A transfective type polarizing plate is usually prepared in the backside of a liquid crystal cell and it may form a liquid crystal display unit of a type in which a picture is displayed by an incident light reflected from a view side (display side) when used in a comparatively well-lighted atmosphere. And this unit displays a picture, in a comparatively dark atmosphere, using embedded type light

sources, such as a back light built in backside of a transfective type polarizing plate. That is, the transfective type polarizing plate is useful to obtain of a liquid crystal display of the type that saves energy of light sources, such as a back light, in a well-lighted atmosphere, and can be used with a built-in light source if needed in a comparatively dark atmosphere etc.

The above-mentioned polarizing plate may be used as elliptically polarizing plate or circularly polarizing plate on which the retardation plate is laminated. A description of the above-mentioned elliptically polarizing plate or circularly polarizing plate will be made in the following paragraph. These polarizing plates change linearly polarized light into elliptically polarized light or circularly polarized light, elliptically polarized light or circularly polarized light into linearly polarized light or change the polarization direction of linearly polarized light by a function of the retardation plate. As a retardation plate that changes circularly polarized light into linearly polarized light or linearly polarized light into circularly polarized light, what is called a quarter wavelength plate (also called $\lambda/4$ plate) is used. Usually, half-wavelength plate (also called $\lambda/2$ plate) is used, when changing the polarization direction of linearly polarized light.

Elliptically polarizing plate is effectively used to give a monochrome display without above-mentioned coloring by compensating (preventing) coloring (blue or yellow color) produced by birefringence of a liquid crystal layer of a super twisted nematic (STN) type liquid crystal display. Furthermore, a polarizing plate in which three-dimensional refractive index is controlled may also preferably compensate (prevent) coloring produced when a screen of a liquid crystal display is viewed from an oblique direction. Circularly polarizing plate is effectively used, for example, when adjusting a color tone of a picture of a reflection type liquid crystal display that provides a colored picture, and it also has function of antireflection.

As retardation plates, birefringent films obtained by uniaxially or biaxially stretched polymer materials, oriented films of liquid crystal polymers, oriented layers of liquid crystal polymers currently supported with films may be mentioned. A thickness of the retardation plate is also not especially limited, and it is about 20 to 150 μm in general.

As polymer material, for example, there may be mentioned: polyvinyl alcohols, polyvinyl butyrals, polymethyl vinyl ethers, polyhydroxy ethyl acrylates, hydroxyethyl celluloses, hydroxypropyl celluloses, methyl celluloses, polycarbonates, polyallylates, polysulfones, polyethylene terephthalates, polyethylene naphthalates, polyethersulfones, polyphenylene sulfides, polyphenylene oxides, polyallyl sulfones, polyamides, polyimides, polyolefins, polyvinyl chlorides, cellulose type polymers, and norbornene based resins, or binary or ternary copolymers, graft copolymers, and blend object thereof. These polymer materials are stretched to obtain an oriented object that is stretched film.

As liquid crystalline polymers, for example, various kinds of polymers of principal chain type and side chain type in which conjugated linear atomic groups (mesogens) conferring liquid crystalline orientation are introduced into a principal chain and a side chain of a polymer may be mentioned. As examples of principal chain type liquid crystalline polymers, polymers having a structure where mesogen groups are bonded by spacer parts conferring flexibility, for example, polyester based liquid crystalline polymers having nematic orientation property, discotic polymers, cholesteric polymers, etc. may be mentioned. As examples of side chain type liquid crystalline polymers, polymers having polysiloxanes, polyacrylates, polymethacrylates, or polymalonates as a principal chain skeleton, and having mesogen parts comprising

para-substituted cyclic compound units conferring nematic orientation property as side chains via spacer parts comprising conjugated atomic groups may be mentioned. These liquid crystal polymer, for example, is aligned by developing a solution of a liquid crystal polymer on an orientation treated surface where rubbing treatment was performed to a surface of thin films, such as polyimide and polyvinyl alcohol, formed on a glass plate, or where silicon oxide is deposited by an oblique evaporation method, and then by heat-treating.

Retardation plates that have suitable phase difference depending on the purpose of use, such as aiming at compensation of coloring or viewing angle using birefringence, for example, various wavelength plates and liquid crystal layers, may be used. In addition retardation plates in which two or more kinds of retardation plates are laminated together to control optical properties, such as phase difference may be used.

The above-mentioned elliptically polarizing plate and an above-mentioned reflected type elliptically polarizing plate are laminated plate combining suitably a polarizing plate or a reflection type polarizing plate with a retardation plate. This type of elliptically polarizing plate etc. may be manufactured by combining a polarizing plate (reflected type) and a retardation plate, and by laminating them one by one separately in the manufacture process of a liquid crystal display. On the other hand, the polarizing plate in which lamination was beforehand carried out and was obtained as an optical film, such as an elliptically polarizing plate, is excellent in a stable quality, a workability in lamination etc., and has an advantage in improved manufacturing efficiency of a liquid crystal display.

A viewing angle compensation film is a film for extending viewing angle so that a picture may look comparatively clearly, even when it is viewed from an oblique direction not from vertical direction to a screen. As such a viewing angle compensation retardation plate, in addition, a film having birefringence property that is processed by uniaxial stretching or orthogonal biaxial stretching and a bi-directional stretched film as inclined orientation film etc. may be used. As inclined orientation film, for example, a film obtained using a method in which a heat shrinking film is adhered to a polymer film, and then the combined film is heated and stretched or shrunk under a condition of being influenced by a shrinking force, or a film that is oriented in oblique direction may be mentioned. The viewing angle compensation film is suitably combined for the purpose of prevention of coloring caused by change of visible angle based on retardation by liquid crystal cell etc. and of expansion of viewing angle with good visibility.

Besides, a compensation plate in which an optical anisotropy layer consisting of an alignment layer of liquid crystal polymer, especially consisting of an inclined alignment layer of discotic liquid crystal polymer is supported with triacetyl cellulose film may preferably be used from a viewpoint of attaining a wide viewing angle with good visibility.

The polarizing plate with which a polarizing plate and a brightness enhancement film are adhered together is usually used being prepared in a backside of a liquid crystal cell. A brightness enhancement film shows a characteristic that reflects linearly polarized light with a predetermined polarization axis, or circularly polarized light with a predetermined direction, and that transmits other light, when natural light by back lights of a liquid crystal display or by reflection from a back-side etc., comes in. The polarizing plate, which is obtained by laminating a brightness enhancement film to a polarizing plate, thus does not transmit light without the predetermined polarization state and reflects it, while obtain-

ing transmitted light with the predetermined polarization state by accepting a light from light sources, such as a backlight. This polarizing plate makes the light reflected by the brightness enhancement film further reversed through the reflective layer prepared in the backside and forces the light re-enter into the brightness enhancement film, and increases the quantity of the transmitted light through the brightness enhancement film by transmitting apart or all of the light as light with the predetermined polarization state. The polarizing plate simultaneously supplies polarized light that is difficult to be absorbed in a polarizer, and increases the quantity of the light usable for a liquid crystal picture display etc., and as a result luminosity may be improved. That is, in the case where the light enters through a polarizer from backside of a liquid crystal cell by the back light etc. without using a brightness enhancement film, most of the light, with a polarization direction different from the polarization axis of a polarizer, is absorbed by the polarizer, and does not transmit through the polarizer. This means that although influenced with the characteristics of the polarizer used, about 50 percent of light is absorbed by the polarizer, the quantity of the light usable for a liquid crystal picture display etc. decreases so much, and a resulting picture displayed becomes dark. A brightness enhancement film does not enter the light with the polarizing direction absorbed by the polarizer into the polarizer but reflects the light once by the brightness enhancement film, and further makes the light reversed through the reflective layer etc. prepared in the backside to re-enter the light into the brightness enhancement film. By this above-mentioned repeated operation, only when the polarization direction of the light reflected and reversed between the both becomes to have the polarization direction which may pass a polarizer, the brightness enhancement film transmits the light to supply it to the polarizer. As a result, the light from a backlight may be efficiently used for the display of the picture of a liquid crystal display to obtain a bright screen.

A diffusion plate may also be prepared between brightness enhancement film and the above described reflective layer, etc. A polarized light reflected by the brightness enhancement film goes to the above described reflective layer etc., and the diffusion plate installed diffuses passing light uniformly and changes the light state into depolarization at the same time. That is, the diffusion plate returns polarized light to natural light state. Steps are repeated where light, in the unpolarized state, i.e., natural light state, reflects through reflective layer and the like, and again goes into brightness enhancement film through diffusion plate toward reflective layer and the like. Diffusion plate that returns polarized light to the natural light state is installed between brightness enhancement film and the above described reflective layer, and the like, in this way, and thus a uniform and bright screen may be provided while maintaining brightness of display screen, and simultaneously controlling non-uniformity of brightness of the display screen. By preparing such diffusion plate, it is considered that number of repetition times of reflection of a first incident light increases with sufficient degree to provide uniform and bright display screen conjointly with diffusion function of the diffusion plate.

The suitable films are used as the above-mentioned brightness enhancement film. Namely, multilayer thin film of a dielectric substance; a laminated film that has the characteristics of transmitting a linearly polarized light with a predetermined polarizing axis, and of reflecting other light, such as the multilayer laminated film of the thin film having a different refractive-index anisotropy (D-BEF and others manufactured by 3M Co., Ltd.); an aligned film of cholesteric liquid-crystal polymer; a film that has the characteristics of

reflecting a circularly polarized light with either left-handed or right-handed rotation and transmitting other light, such as a film on which the aligned cholesteric liquid crystal layer is supported (PCF350 manufactured by NITTO DENKO CORPORATION, Transmax manufactured by Merck Co., Ltd., and others); etc. may be mentioned.

Therefore, in the brightness enhancement film of a type that transmits a linearly polarized light having the above-mentioned predetermined polarization axis, by arranging the polarization axis of the transmitted light and entering the light into a polarizing plate as it is, the absorption loss by the polarizing plate is controlled and the polarized light can be transmitted efficiently. On the other hand, in the brightness enhancement film of a type that transmits a circularly polarized light as a cholesteric liquid-crystal layer, the light may be entered into a polarizer as it is, but it is desirable to enter the light into a polarizer after changing the circularly polarized light to a linearly polarized light through a retardation plate, taking control an absorption loss into consideration. In addition, a circularly polarized light is convertible into a linearly polarized light using a quarter wavelength plate as the retardation plate.

A retardation plate that works as a quarter wavelength plate in a wide wavelength ranges, such as a visible-light band, is obtained by a method in which a retardation layer working as a quarter wavelength plate to a pale color light with a wavelength of 550 nm is laminated with a retardation layer having other retardation characteristics, such as a retardation layer working as a half-wavelength plate. Therefore, the retardation plate located between a polarizing plate and a brightness enhancement film may consist of one or more retardation layers.

In addition, also in a cholesteric liquid-crystal layer, a layer reflecting a circularly polarized light in a wide wavelength ranges, such as a visible-light band, may be obtained by adopting a configuration structure in which two or more layers with different reflective wavelength are laminated together. Thus a transmitted circularly polarized light in a wide wavelength range may be obtained using this type of cholesteric liquid-crystal layer.

Moreover, the polarizing plate may consist of multi-layered film of laminated layers of a polarizing plate and two of more of optical layers as the above-mentioned separated type polarizing plate. Therefore, a polarizing plate may be a reflection type elliptically polarizing plate or a semi-transmission type elliptically polarizing plate, etc. in which the above-mentioned reflection type polarizing plate or a transmissive type polarizing plate is combined with above described retardation plate respectively.

Although an optical film with the above described optical layer laminated to the polarizing plate may be formed by a method in which laminating is separately carried out sequentially in manufacturing process of a liquid crystal display etc., an optical film in a form of being laminated beforehand has an outstanding advantage that it has excellent stability in quality and assembly workability, etc., and thus manufacturing processes ability of a liquid crystal display etc. may be raised. Proper adhesion means, such as an adhesive layer, may be used for laminating. On the occasion of adhesion of the above described polarizing plate and other optical films, the optical axis may be set as a suitable configuration angle according to the target retardation characteristics etc.

A method for producing the antistatic pressure-sensitive adhesive optical film according to the present invention will be described hereinafter.

For example, an application liquid containing a conductive polymer and a sulfonic acid compound is applied to the opti-

cal film **1** described above, and dried to form an antistatic layer **2**. The solid concentration of the application liquid is preferably adjusted to approximately 0.5 to 5% by weight. Firstly, the application liquid is applied to the optical film **1** using application methods, roll coating methods such as a reverse coating and a gravure coating; a spin coating method; a screen coating method; a fountain coating method; a dipping method; a spray method, etc., and then dried to obtain an antistatic layer.

The thickness of the antistatic layer is preferably 5 to 1000 nm. In consideration of optical property deterioration, the thickness of the antistatic layer is usually 5000 nm or less. Thicker antistatic layers may easily cause possible breakage within the antistatic layer due to insufficient strength of the antistatic layer, and may not provide sufficient adhesion. The thickness of the antistatic agent is 500 nm or less, preferably 300 nm or less, and more preferably 200 nm or less. In consideration of guarantee of adhesion, and suppression of peeling electrification, the thickness is 5 nm or more, and preferably 10 nm or more. On the other hand, the thicker antistatic layer gives the more preferable suppression effect of peeling electrification, but the thickness exceeding 200 nm can only give the same or less in suppression effect of peeling electrification. In consideration of such a point, the thickness is 5 to 500 nm, preferably 10 to 300 nm, and more preferably 10 to 200 nm.

In formation of the antistatic layer **2**, an activation treatment may be performed with respect to the optical film **1**. As the activation treatment, various methods, for example, corona treatment, low-pressure UV treatment, plasma treatment, etc., are employable. When using an aqueous solution containing an electric conductive polymer as an antistatic agent, the activation treatment is effective, and can suppress repelling of the aqueous solution in application. The activation treatment is especially effective, when the optical film **1** is of polyolefin-based resin and norbornene-based resin.

Formation of the pressure-sensitive adhesive layer **3** is performed by lamination onto the above-mentioned antistatic layer **2**. Formation methods are not especially limited, and there may be adopted: a method in which a pressure-sensitive adhesive solution is applied onto an antistatic layer, and then is dried; and a method of transfer using a releasing sheet having a pressure-sensitive adhesive layer formed thereon etc. A thickness of the pressure-sensitive adhesive layer is not especially limited; it is preferably about 10 to 40 μ m.

As components of the releasing sheet, there may be mentioned suitable sheeted materials: papers; synthetic resin films, such as polyethylenes, polypropylenes, and polyethylene terephthalates; rubber sheets; papers; cloths; nonwoven fabrics; nets; foamed sheets; metallic foils; and laminated materials of the above-mentioned materials, etc. In order to increase releasability from the pressure-sensitive adhesive layer **3**, releasing treatment giving low adhesive properties, such as a siliconization, a long chain alkyl treatment, and a fluorine treatment, may be performed to a surface of the releasing sheet if needed.

In addition, in the present invention, ultraviolet absorbing property may be given to the above-mentioned each layer, such as antistatic pressure-sensitive adhesive optical film, an optical film etc. and an adhesive layer, using a method of adding UV absorbents, such as salicylic acid ester type compounds, benzophenol type compounds, benzotriazol type compounds, cyano acrylate type compounds, and nickel complex salt type compounds.

The adhering strength between the antistatic layer **2** and the pressure-sensitive adhesive layer **3** preferably has a peeling angle of 180° C., and it preferably has adhering strength of 18

17

N/25 mm or more at a peeling rate of 300 mm/min, and more preferably 20 N/25 mm or more. The adhering strength less than 18N/25 mm may cause adhesive residue in the case of peeling of the optical film from the liquid crystal panel, leading to possible peeling under heated condition and wet and heated condition.

An antistatic pressure-sensitive adhesive optical film of the present invention may be preferably used for manufacturing various equipment, such as liquid crystal display, etc. Assembling of a liquid crystal display may be carried out according to conventional methods. That is, a liquid crystal display is generally manufactured by suitably assembling several parts such as a liquid crystal cell, optical films and, if necessity, lighting system, and by incorporating driving circuit. In the present invention, except that the optical film by the present invention is used, there is especially no limitation to use any conventional methods. Also any liquid crystal cell of arbitrary type, such as TN type, and STN type, π type may be used.

Suitable liquid crystal displays, such as liquid crystal display with which the above-mentioned antistatic pressure-sensitive adhesive optical film has been located at one side or both sides of the liquid crystal cell, and with which a backlight or a reflector is used for a lighting system may be manufactured. In this case, the antistatic pressure-sensitive adhesive optical film by the present invention may be installed in one side or both sides of the liquid crystal cell. When installing the optical films in both sides, they may be of the same type or of different type. Furthermore, in assembling a liquid crystal display, suitable parts, such as diffusion plate, anti-glare layer, antireflection film, protective plate, prism array, lens array sheet, optical diffusion plate, and backlight, may be installed in suitable position in one layer or two or more layers.

Subsequently, organic electro luminescence equipment (organic EL display) will be explained. Generally, in organic EL display, a transparent electrode, an organic emitting layer and a metal electrode are laminated on a transparent substrate in an order configuring an illuminant (organic electro luminescence illuminant) Here, an organic emitting layer is a laminated material of various organic thin films, and such compositions with various combination are known, for example, a laminated material of hole injection layer comprising triphenylamine derivatives etc., an emitting layer comprising fluorescent organic solids, such as anthracene; a laminated material of electronic injection layer comprising such an emitting layer and perylene derivatives, etc.; laminated material of these hole injection layers, emitting layer, and electronic injection layer etc.

An organic EL display emits light based on a principle that positive hole and electron are injected into an organic emitting layer by impressing voltage between a transparent electrode and a metal electrode, the energy produced by recombination of these positive holes and electrons excites fluorescent substance, and subsequently light is emitted when excited fluorescent substance returns to ground state. A mechanism called recombination which takes place in an intermediate process is the same as a mechanism in common diodes, and, as is expected, there is a strong non-linear relationship between electric current and luminescence strength accompanied by rectification nature to applied voltage.

In an organic EL display, in order to take out luminescence in an organic emitting layer, at least one electrode must be transparent. The transparent electrode usually formed with transparent electric conductor, such as indium tin oxide (ITO), is used as an anode. On the other hand, in order to make electronic injection easier and to increase luminescence efficiency, it is important that a substance with small work func-

18

tion is used for cathode, and metal electrodes, such as Mg—Ag and Al—Li, are usually used.

In organic EL display of such a configuration, a very thin film about 10 nm forms an organic emitting layer in thickness. For this reason, light is transmitted nearly completely through organic emitting layer as through transparent electrode. Consequently, since the light that enters, when light is not emitted, as incident light from a surface of a transparent substrate and is transmitted through a transparent electrode and an organic emitting layer and then is reflected by a metal electrode, appears in front surface side of the transparent substrate again, a display side of the organic EL display looks like mirror if viewed from outside.

In an organic EL display containing an organic electro luminescence illuminant equipped with a transparent electrode on a surface side of an organic emitting layer that emits light by impression of voltage, and at the same time equipped with a metal electrode on a back side of organic emitting layer, a retardation plate may be installed between these transparent electrodes and a polarizing plate, while preparing the polarizing plate on the surface side of the transparent electrode.

Since the retardation plate and the polarizing plate have function polarizing the light that has entered as incident light from outside and has been reflected by the metal electrode, they have an effect of making the mirror surface of metal electrode not visible from outside by the polarization action. If a retardation plate is configured with a quarter wavelength plate and the angle between the two polarization directions of the polarizing plate and the retardation plate is adjusted to $\pi/4$, the mirror surface of the metal electrode may be completely covered.

This means that only linearly polarized light component of the external light that enters as incident light into this organic EL display is transmitted with the work of polarizing plate. This linearly polarized light generally gives an elliptically polarized light by the retardation plate, and especially the retardation plate is a quarter wavelength plate, and moreover when the angle between the two polarization directions of the polarizing plate and the retardation plate is adjusted to $\pi/4$, it gives a circularly polarized light.

This circularly polarized light is transmitted through the transparent substrate, the transparent electrode and the organic thin film, and is reflected by the metal electrode, and then is transmitted through the organic thin film, the transparent electrode and the transparent substrate again, and is turned into a linearly polarized light again with the retardation plate. And since this linearly polarized light lies at right angles to the polarization direction of the polarizing plate, it cannot be transmitted through the polarizing plate. As the result, mirror surface of the metal electrode may be completely covered.

EXAMPLE

The present invention will be described specifically with reference to examples hereinafter, but the present invention is not limited by these examples. Both of parts and % in each example are based on weight.

(Production of Polarizing Plate)

A polyvinyl alcohol film having a thickness of 80 μm was stretched 5 times in a 40° C. iodine aqueous solution, and subsequently was dried for 4 minutes at 50° C. to obtain a polarizer. A triacetyl cellulose film was adhered on both sides

19

of this polarizer using a polyvinyl alcohol-based pressure-sensitive adhesive to obtain a polarizing plate.

Example 1

Formation of Antistatic Layer

An aqueous solution (0.8% of solid content) containing 3 parts of poly(3,4-ethylene dioxythiophene) as a conductive polymer, 100 parts of a polyester resin as a binder component, and 5 parts of polystyrene sulfonic acid was prepared. The aqueous solution concerned was applied to one side of the polarizing plate so that the thickness after drying might give 80 nm, and the applied layer was dried by heating for 2 minutes at 80° C., and an antistatic layer was formed.

(Formation of a Pressure-Sensitive Adhesive Layer)

An amount of 95 parts of butyl acrylate, 15 parts of N-cyclohexylmaleimide, 5 parts of hydroxyethyl acrylate, and 0.2 parts of benzoyl peroxide were dissolved in 300 parts of toluene as a base polymer, the reaction was continued at about 60° C. for 6 hours under agitation. Thus, a solution (25% of solid content) containing an acryl-based polymer containing nitrogen with a weight average molecular weight of 2 million was prepared. As an isocyanate-based cross-linking agent, 0.5 part of Coronate L manufactured by NIPPON POLYURETHANE INDUSTRY CO., LTD., with respect to 100 parts of polymer solid content was added to the above-described solution of the acryl-based polymer containing nitrogen to obtain a pressure-sensitive adhesive solution (12% of solid content). The pressure-sensitive adhesive solution concerned was applied by a reverse roll coating method to a release sheet (product made by MITSUBISHI POLYESTER FILM CORPORATION, DIAFOIL MRF38, polyethylene terephthalate base material) so as to have a thickness after dried of 25 μ m. Subsequently, a release sheet was further given on the applied solution, the material obtained was dried in hot air circulating oven, and a pressure-sensitive adhesive layer was formed.

(Production of an Antistatic Pressure-Sensitive Adhesive Optical Film)

The release sheet having the pressure-sensitive adhesive layer formed thereon was attached on the antistatic layer of the above-described antistatic polarizing plate. The obtained sheet was aged for one week at a room temperature, and an antistatic pressure-sensitive adhesive polarizing plate was thus obtained.

Example 2

Except for having used 5 parts of N-phenylmaleimide instead of N-cyclohexylmaleimide in formation of the pressure-sensitive adhesive layer in Example 1, an antistatic pressure-sensitive adhesive polarizing plate was produced by the same method as in Example 1.

Example 3

Except for having used 25 parts of N-acryloyl morpholine instead of N-cyclohexylmaleimide in formation of the pressure-sensitive adhesive layer of Example 1, an antistatic pressure-sensitive adhesive polarizing plate was produced by the same method as in Example 1.

Example 4

Except for having used 3 parts of polystyrene sulfonic acid in formation of the antistatic layer of Example 1, an antistatic

20

pressure-sensitive adhesive polarizing plate was produced by the same method as in Example 1.

Example 5

Except for having used 7.5 parts of polystyrene sulfonic acid in formation of the antistatic layer of Example 1, an antistatic pressure-sensitive adhesive polarizing plate was produced by the same method as in Example 1.

Comparative Example 1

Except for not having used N-cyclohexylmaleimide in formation of the pressure-sensitive adhesive layer of Example 1, an antistatic pressure-sensitive adhesive polarizing plate was produced by the same method as in Example 1.

Comparative Example 2

Except for not having formed an antistatic layer in Example 1, a pressure-sensitive adhesive polarizing plate was produced by the same method as in Example 1.

Following evaluations were performed about the antistatic pressure-sensitive adhesive optical films obtained by Examples and Comparative examples. Table 1 illustrates evaluation results.

[Adhesion]

The produced antistatic pressure-sensitive adhesive optical films were cut into pieces with 25 mm width×50 mm length. A side of the pressure-sensitive adhesive layer and was attached to a vapor-deposited side of a vapor deposition film obtained by vacuum deposition of indium tin oxide on a surface of a polyethylene terephthalate film having a thickness of 50 μ m, and was kept standing under conditions of 23° C./60% RH for 20 minutes or more. Subsequently, the edge of the polyethylene terephthalate film was peeled by hand, adhesion of the pressure-sensitive adhesive on the side of the polyethylene terephthalate film was confirmed, and the adhering strength 180° peeling (N/25 mm) between the antistatic layer and the pressure-sensitive adhesive layer was evaluated for using a tensile testing machine (made by Shimadzu Corp., AUTOGRAPH AG-1), under a room temperature atmosphere (25° C.) at a speed of testing of 300 mm/min.

[Water Resistance]

(Warm Water Immersion)

The produced antistatic pressure-sensitive adhesive optical film was cut into a size of 100 mm×100 mm to obtain a sample. The pressure-sensitive adhesive layer of the sample was attached to an alkali free glass (made by Dow Corning Corporation) and was immersed in 40° C. warm water for 10 hours for evaluation of peeling by visual inspection.

[Antistatic Effect]

The produced antistatic pressure-sensitive adhesive optical film was cut into a size of 100 mm×100 mm, and was attached on a liquid crystal panel. This panel was placed on a backlight having a luminance of 10000 cd, and static electricity of 5 kv was applied using an ESD (product made by SANKI Co., Ltd., ESD-8012A) as a static electricity generator to cause alignment disorder of the liquid crystal. The recovery period of time (second) of the display defect by the alignment defect was measured for using an instantaneous multi-photometry detector (made by OTSUKA ELECTRONICS CO., LTD., MCPD-3000).

What is claimed is:

1. An antistatic pressure-sensitive adhesive optical film, the optical film having an antistatic layer laminated on at least one side of the optical film, and a pressure-sensitive adhesive layer further laminated on the antistatic layer,

wherein the antistatic layer comprises a water soluble or water dispersible polythiophene conductive polymer and a sulfonic acid compound as raw material components, and the pressure-sensitive adhesive layer is formed of an acryl-based pressure-sensitive adhesive containing nitrogen,

wherein the optical film is selected from the group consisting of a polarizing plate, a retardation plate, an optical compensation film, a brightness enhancement film, and a laminate thereof,

wherein a base polymer of the acryl-based pressure-sensitive adhesive containing nitrogen is a copolymer of a monomer containing nitrogen and an acryl-based monomer, or a mixture of a polymer containing nitrogen and an acryl-based polymer,

wherein the polymer containing nitrogen comprises the monomer containing nitrogen,
wherein the monomer containing nitrogen is N-acryloylmorpholine,

wherein the antistatic layer is on and in direct contact with the optical film, and

wherein the pressure-sensitive adhesive layer is on and in direct contact with the antistatic layer.

2. The antistatic pressure-sensitive adhesive optical film according to claim 1, wherein the sulfonic acid compound is a water soluble sulfonic acid compound.

3. The antistatic pressure-sensitive adhesive optical film according to claim 1, wherein the antistatic layer comprises 100 to 300 parts by weight of the sulfonic acid compound with respect to 100 parts by weight of the conductive polymer.

22

4. The antistatic pressure-sensitive adhesive optical film according to claim 1, wherein the acryl-based pressure-sensitive adhesive comprises the copolymer of a monomer containing nitrogen and an acryl-based monomer.

5. The antistatic pressure-sensitive adhesive optical film according to claim 1, wherein the acryl-based pressure-sensitive adhesive comprises the mixture of a polymer containing nitrogen and an acryl-based polymer.

6. The antistatic pressure-sensitive optical film according to claim 5, wherein the polymer containing nitrogen is present at 0.5 to 50 parts by weight with respect to 100 parts by weight of the acryl-based polymer.

7. The antistatic pressure-sensitive adhesive optical film according to claim 1, wherein the pressure-sensitive adhesive layer consists of a single pressure sensitive adhesive layer, wherein the acryl-based pressure-sensitive adhesive comprises an acrylic copolymer, and wherein the acrylic copolymer does not contain a carboxyl group-containing monomer.

8. The antistatic pressure-sensitive optical film according to claim 1, wherein the optical film and the pressure-sensitive adhesive layer are the outermost layers of the antistatic pressure-sensitive adhesive optical film.

9. An image viewing display using at least one of the antistatic pressure-sensitive adhesive optical film according claim 1.

10. An antistatic pressure-sensitive adhesive optical film comprising:

(a) an optical film;

(b) an antistatic layer, comprising a conductive polymer and a sulfonic acid compound as raw material components, laminated on at least one side of the optical film; and

(c) a pressure-sensitive adhesive layer, comprising an acryl-based pressure-sensitive adhesive containing nitrogen, laminated on the antistatic layer,

wherein the antistatic layer is on and in direct contact with the optical film, and

wherein the pressure-sensitive adhesive layer is on and in direct contact with the antistatic layer.

11. The antistatic pressure-sensitive adhesive optical film according to claim 10, wherein the pressure-sensitive adhesive layer consists of a single pressure sensitive adhesive layer, wherein the acryl-based pressure-sensitive adhesive comprises an acrylic copolymer, and wherein the acrylic copolymer does not contain a carboxyl group-containing monomer.

12. The antistatic pressure-sensitive optical film according to claim 10, wherein the optical film and the pressure-sensitive adhesive layer are the outermost layers of the antistatic pressure-sensitive adhesive optical film.
